

(a) Estimated per-branch kappa (b) Internal node age estimates against the age of each branch. under the two models. Each point is the posterior mean point is one internal node, with its of the kappa parameter for one age under the base (single-kappa) branch, shown on a logarithmic model on the horizontal axis and scale; the vertical bars show its age under the per-branch kappa 95% credible interval and the horizontal bars show the 95% credible interval of the age. Age is the height of the branch's midpoint interval, and the dotted line is above the present, measured in expected substitutions per site (the tree is estimated in units of substitutions and is not calibrated to time).
